HW04 Functional Data Analysis

Drew Remmenga

2022-10-08

- You are encouraged to use web resources and class materials
- You can work in a group but hand in your assignment as an individual.
- Be spare in what you include and you will lose credit if you include too much extraneous output or information. All questions count for an equal number of points.
- Any subproblems marked GRAD are required for 500 level students but will serve as an extra credit question for the 400 level students.
- Please send me email if you have questions or any concerns. nychka@mines.edu
- Hand in your work in pdf format in Gradescope. You can keep the questions as part of what you hand in but you should begin your *answer* on a separate page. You can use \newpage to create a page break in your work.
- To comment out the answers without just deleting them use the html commenting format

```
<!-- This text is now commented out and will not be part of the rendered output. \leftarrow->
```

and check this Rmarkdown document for more details.

Points

All subsections of the problems count equally for 10 points:

- 400 level 1(30), 2(40)
- 500 level 1(40), 2(40)

Some setup

```
suppressMessages(library( fields))
## Warning: package 'fields' was built under R version 4.1.3
## Warning: package 'spam' was built under R version 4.1.3
```

Problem 1

This problem will give you practice setting up and interpreting a Monte Carlo study of a statistical method. This one looks at how well the GCV criterion works in choosing a good data based smoothing parameter, lambda.

Refer back to the R script **4.3cubicSmoothingSpline.R** as an example. Even though the smoothing is controlled in a spline by the lambda parameter, note that throughout we looking at effective degrees of freedom as a more useful measure of the amount of smoothing rather than the lambda value itself. One can go back and forth between these two version in the same way one can look at a logged or unlogged value.

Given below is a breakdown of the steps (A-E) to do this. Some of you may already be familiar with this setup but it is detailed here for completeness.

Recall that a test function and data are created using the code

```
set.seed(123)
N <- 150
s <- runif(N)
s <- sort(s)
# asymetric bump function is the true curve
true <- 9 * s * (1 - s) ^ 3
errors<- .1 * rnorm(N)
y <- true + errors</pre>
```

```
EffDF<- rep( NA, 200)
MSE1<- rep( NA, 200)
MSE2<- rep( NA, 200)

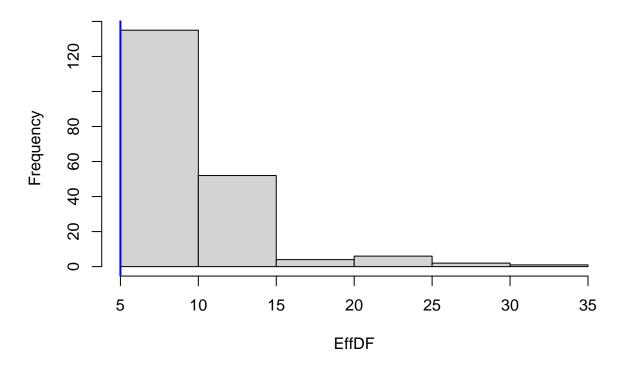

set.seed(498)
errors<- matrix( .1 * rnorm(N*200), N, 200)
Y <- true + errors
for( k in 1:200)
{
fitObjFixed<- Tps(s,Y[,k],df=5)
fitObjGCV<- Tps(s,Y[,k])
EffDF[k]<- fitObjGCV\setf.df
fHatFixed<- predict( fitObjFixed)
fHatGCV<- predict( fitObjGCV)
MSE1[k]<- mean( (true - fHatFixed)^2 )
MSE2[k]<- mean( (true - fHatGCV)^2 )
}</pre>
```

1(a)

Across the 200 samples, is there a difference between the the EffDF found by GCV and the fixed value at 5? Use a histogram and a vertical line at 5 to explain your results. There is a large difference. The effdf caused by GCV is seewed heavily to the right.

```
hist(EffDF)
abline(v=5,col="blue",lwd=2)
```

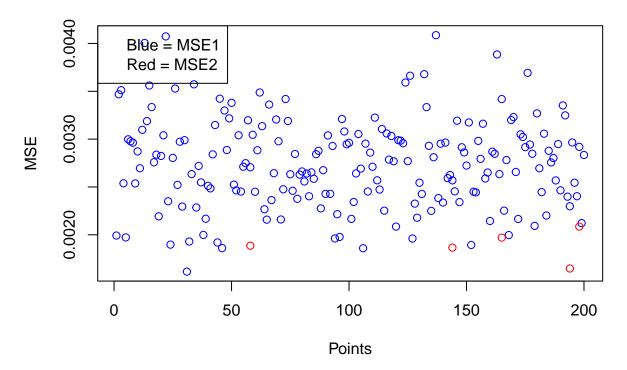

Histogram of EffDF

1(b) Based on the mean squared error which is a more accurate estimate of the true curve, effDF=5 or GCV? MSE based on GCV has a lower value so it is more accurate.

```
plot(MSE1, main = "MSE1 vs MSE2", xlab= "Points",ylab = "MSE", col="Blue")
points(MSE2, col="Red")
legend("topleft", legend = c("Blue = MSE1", "Red = MSE2"))
```

MSE1 vs MSE2

1(c) Is there any dependence between the effective DF from GCV and the corresponding MSE. When does the estimated curve do poorly? When there are few degrees of freedom. ## 1(d) GRAD Find the worst MSE out of the 200 samples and go back and look at scatterplot of the generated data and add the two estimated curves using df=5 and GCV. Are there any features that you see in the data to tip you off that GCV not working well?

Problem 2

Revisit the hourly Golden Ozone data for 2021 that you worked on for the take home.

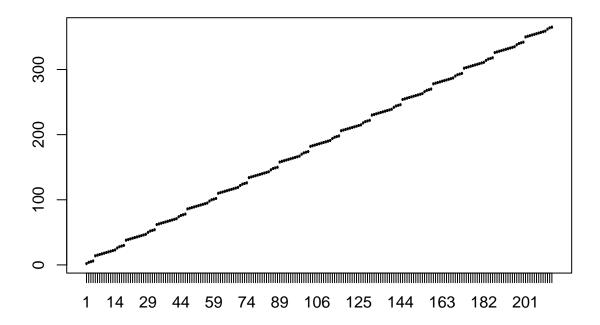

2(a)

Create a matrix where each column indexes a day and the rows are the hourly values. Note that this is similar to the \mathbf{Y} from Problem 1. Also to make this simpler omit all days that do not have a complete set of observations. The code below does this wrangling for you.

```
load("GOzone2021.rda")
library( lubridate)
##
## Attaching package: 'lubridate'
## The following objects are masked from 'package:base':
##
##
       date, intersect, setdiff, union
03<- matrix( NA, nrow=365, ncol=24)
03[cbind(G0zone2021$day, G0zone2021$hour+1)]<- G0zone2021$03
dim( 03)
## [1] 365 24
ind<- colSums( is.na(03)) ==0</pre>
03 < -03[ind,]
tday<- 1:365
tday<- tday[ind]
03<- t( 03)
dim( 03)
## [1] 24 213
sHour<- 0:23
```

Plot these data as individual boxplots over the days of the year (tday). Note that you might have to tranpose the data back to rows with hours and columns of days to use the boxplot function.

```
boxplot(t(tday))
```

2(b) For each day smooth the 24 hourly measurements using a cubic smoothing spline. Find the GCV estimate of the effective degrees of freedom and summarize the results.

To searching for the GCV minimum if it is at either end of the DF range, 2 or n, the Tps function it will give a warning message. Don't worry about getting these except to note some of the searches are finding eff.df that are close to 24. (I see 7 cases with 22.8 being reported as the endpoint.)

```
for( k in 1:200)
fitObjGCV<- Tps(sHour, 03[,k])</pre>
EffDF[k]<- fit0bjGCV$eff.df</pre>
fHatGCV<- predict( fitObjGCV)</pre>
}

##
```

plot(EffDF)

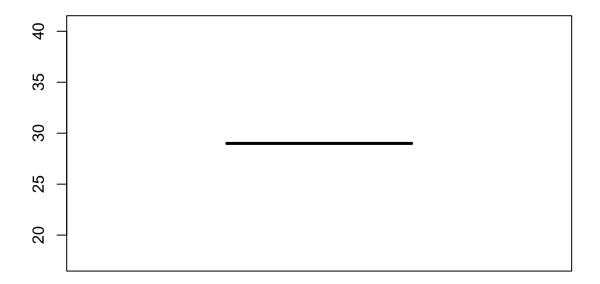

which.max(EffDF)

[1] 1

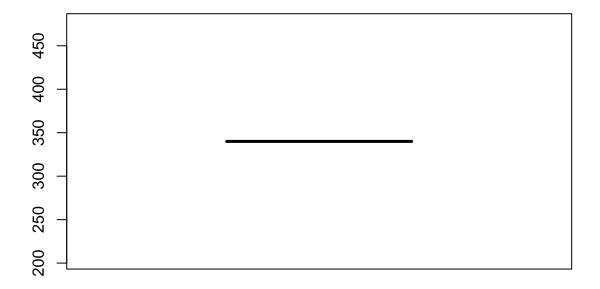

2(c)

From your results in 2(b) identify a day where the effective degrees of freedom is less than 10 and plot the hourly measurements and add the GCV spline. Do the same for a case where the effective degrees of freedom is above 20. In either case, do the smooth curves seem reasonable?

boxplot(tday[17])

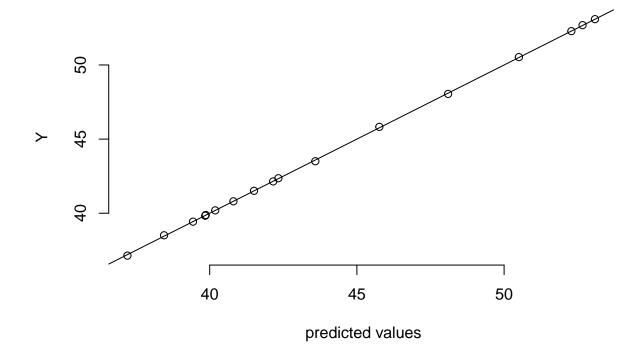

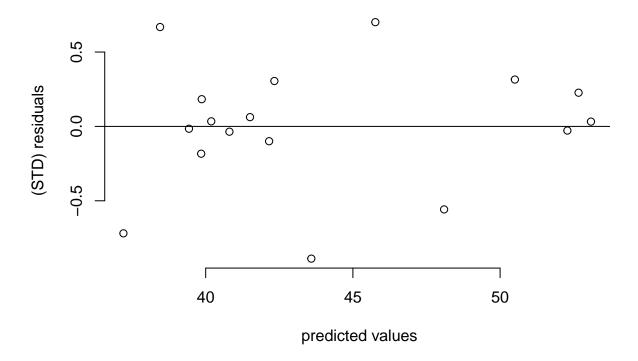

boxplot(tday[198])

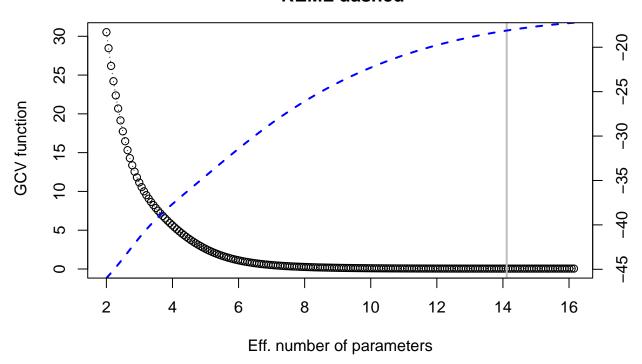

2(d) Find the average of the measurements for each hour across the different day resulting in a data vector of length 24. (for example

```
mean03<- rowMeans(03)
for( k in 1:200)
{
fit0bjGCV<- Tps(sHour,mean03)
EffDF[k]<- fit0bjGCV$eff.df
fHatGCV<- predict( fit0bjGCV)
}
plot(fit0bjGCV)</pre>
```

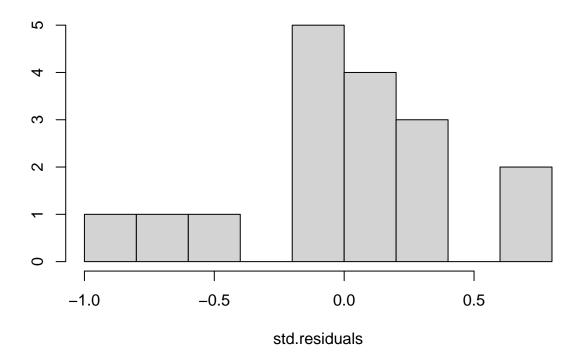

GCV-points, solid-model, dots- single REML dashed

points(mean03)

Histogram of std.residuals

) Smooth these data with a cubic smoothing spline using GCV, create a scatter plot of the data and add the fitted curve. Compare the effective degrees of freedom found in this case to the ones above. The degrees of freedom are fewer. ## 2(e) EXTRA CREDIT When I work 2(d) I find eff.df is about 14.1. Return to 2(b) and use this value for all the days in the Tps function. For either case, GCV or df=14.1 save the value of the GCV criteria found for the curve. Compute the GCV criterion for either case "by hand" For example

```
look<- Tps(sHour, 03[,k])
n<- length( sHour)
GCV[k]<- mean( look$residuals^2)/ (1- look$eff.df/n)^2</pre>
```

Compare the GCV values for the fixed degrees of freedom at 14.1 to the GCV when it is minimized across all the days in the data set. How different are they? Does it suggest 14.1 might be a good fixed choice?
